Gravimetric analysis is a quantitative method for accurately determining the amount of a substance by selective precipitation of the substance from an aqueous solution. The precipitate is separated from the remaining aqueous solution by filtration and is then weighed. Assuming that the chemical formula for the precipitate is known and that the precipitation reaction goes all the way to completion, then the mass of the substance in the original sample can be determined.

determination of an analyte based on its mass. The principle of this type of analysis is that once an ion's mass has been determined as a unique compound, that known measurement can then be used to determine the same analyte's mass in a mixture, as long as the relative quantities of the other constituents are known. The four main types of this method of analysis are precipitation, volatilization, el

Using the analytical balance, weigh 3 individual samples of your unknown, and put each individual sample into its own clean 600 mL beaker. You must weigh the samples to 4 decimal places, and each sample should be between 0.15 and 0.20 grams. Samples slightly above 0.20 grams, or below 0.15 grams, will work.

Let  $x$  gms. be the Na present and  $y$  gms. the K present, and let  $P$  be the weight of two atoms of Na ( $P = Na_2 = 46$ ) and  $Q$  that of K ( $Q = K_2 = 78$ ) and  $R$  the molecular weight of  $SO_4$  ( $R = 96$ ).

### **Gravimetric Analysis Precipitation Reactions Examples**

An accurate gravimetric analysis requires that the analytical signal—whether it is a mass or a change in mass—be proportional to the amount of analyte in our sample. For all gravimetric methods this proportionality involves a conservation of mass.
